INTRODUCTION

Biscayne Bay and Manatee Bay, Florida were sampled during December 1999. One aspect of this study was benthic community characterization, which was accomplished via sample collection by National Oceanic and Atmospheric Administration (NOAA) personnel and laboratory and data analysis by Barry A. Vittor & Associates, Inc. (BVA).

METHODS

Sample Collection and Handling

A Young dredge (area = 0.04 m²) was used to collect bottom samples at 21 stations in Biscayne Bay and 9 stations in Manatee Bay (Figure 1). Samples were prescreened through 0.5 mm mesh sieves, by NOAA in the field and fixed in 10% formalin. The preserved sample fractions were transported to BVA'S laboratory in Mobile, Alabama.

Macrofaunal Sample Analysis

In BVA's laboratory, benthic samples were inventoried, rinsed gently through a 0.5 mm mesh sieve to remove preservatives and sediment, stained with Rose Bengal, and stored in 70% isopropanol solution until processing. Sample material (sediment, detritus, organisms) was placed in white enamel trays for sorting under Wild M-5A dissecting microscopes. All macroinvertebrates were carefully removed with forceps and placed in labeled glass vials containing 70% isopropanol. Each vial represented a major taxonomic group (*e.g.* Polychaeta, Mollusca, Arthropoda). All sorted macroinvertebrates were identified to the lowest practical identification level (LPIL), which in most cases was to species level unless the specimen was a juvenile, damaged, or otherwise unidentifiable. The number of individuals of each taxon, excluding fragments, was recorded. A voucher collection was prepared, composed of representative individuals of each species not previously encountered in samples from the region.

DATA ANALYSIS

All data generated as a result of laboratory analysis of macrofaunal samples were first coded on data sheets. Enumeration data were entered for each species according to station and replicate. These data were reduced to a data summary report for each station, which included a taxonomic species list and benthic community parameters information. Archive data files of species identification and enumeration were prepared.

The Quality Assurance/Quality Control (QA/QC) reports for the Biscayne and Manatee Bay samples are given in Appendix I. Quality control comments for common LPIL taxa are given in Appendix II.

Assemblage Structure

Several numerical indices were chosen for analysis and interpretation of the macrofaunal data. Infaunal abundance is reported as the total number of individuals per station and the total number of individuals per square meter (= density). Taxa richness is reported as the total number of taxa represented in a given station collection.

Taxa diversity, which is often related to the ecological stability and environmental "quality" of the benthos, was estimated by the Shannon-Weaver Index (Pielou, 1966), according to the following formula:

$$H' = - \sum_{i=1}^S p_i (\ln p_i)$$

where, S = the number of taxa in the sample,

i = the i'th taxon in the sample, and

p_i = the number of individuals of the i'th taxon divided by the total number of individuals in the sample.

Taxa diversity within a given community is dependent upon the number of taxa present (taxa richness) and the distribution of all individuals among those taxa (equitability or evenness). In order to quantify and compare faunal equitability to taxa diversity for a given area, Pielou's Evenness Index J' (Pielou, 1966) was calculated as $J' =$

$H'/\ln S$, where $\ln S = H'_{\max}$, or the maximum possible diversity, when all taxa are represented by the same number of individuals; thus, $J' = H' /H'_{\max}$.

HABITAT CHARACTERISTICS

Water quality data for the 30 stations are presented in Table 1 and Figures 2 and 3. Bottom salinity ranged from 12.6 ppt to 21.0 ppt for the shoreline Stations 1-5 and between 19 ppt and 35 ppt for the remaining stations in Biscayne Bay (Table 1, Figure 2). Salinity in Manatee Bay was > than 20 ppt for all stations (Table 1, Figure 2). Bottom dissolved oxygen data at the Biscayne and Manatee Bay is given in Figure 3.

BENTHIC COMMUNITY CHARACTERIZATION

Faunal Composition, Abundance, and Community Structure

Table 2 provides a complete phylogenetic listing for the Biscayne Bay and Manatee Bay stations as well as data on taxa abundance and strata occurrence. Microsoft Excel spreadsheets will be provided separately to NOAA including a raw data table containing taxa abundance and density data and all report tables.

A total of 14,051 organisms, representing 392 taxa, were identified from the 30 stations (Table 3). Polychaetes were the most numerous organisms present representing 41.3% of the total assemblage, followed in abundance by malacostracans (23.2%), gastropods (15.6%), and bivalves (11%). Polychaetes represented 31.8% of the total number of taxa followed by bivalves (21.4%), malacostracans (21.1%) and gastropods (15.2%)(Table 3). The percentage abundance of the major taxa at the 30 stations is given in Table 4 and Figure 4.

The dominant taxa collected from the 21 Biscayne Bay stations were the gastropod, *Caecum pulchellum*, the malacostracan, *Hargeria rapax* and the polychaetes, *Exogone rolani* and *Fabricinuda trilobata*, representing 14.8%, 14.2%, 9.1%, and 5.3% of the total number of individuals, respectively (Table 2). *Hargeria rapa* and the annelid family, Tubificidae (LPIL) were the most widely distributed taxa being found at 95% of the stations. The distribution of taxa representing > 10% of the total assemblage at each

station is given in Table 5. Nearshore stations 1-5 in Biscayne Bay were dominated by a more estuarine fauna (Table 5).

The dominant taxon collected from the 9 Manatee Bay stations was the bivalve, *Brachidontes exustus*, representing 46.1% of the total number of individuals (Table 2). Other common taxa included the gastropod, *Caecum pulchellum*, the arthropod, *Grandidierella bonnieroides*, and the annelid family, Tubificidae (LPIL), representing 7.6%, 5.3%, and 5.2% of the total number of individuals. Tubificids were the most widely distributed taxon being found at 100% of the stations. The stations in Manatee Bay were dominated by a more estuarine fauna than all but the most nearshore stations in Biscayne Bay (Tables 2 and 5). For example, tubificid oligochaetes were the dominant taxa at 4 of the 9 stations, while the chironomid, *Clunio* (LPIL) was abundant at 2 of the 9 stations.

Station abundance and taxa data are summarized for the Biscayne Bay and Manatee Bay stations in Table 6. In Biscayne Bay the number of taxa per station ranged from 13 at Station 16 to 96 at Station 7 (Table 6; Figures 6 and 7). Nearshore stations 1-5 had considerably lower taxa richness than the remaining stations in Biscayne Bay (Table 6, Figures 6 and 7). In Manatee Bay the number of taxa per station ranged from 2 at Station 23 to 74 at Station 29 (Table 6, Figures 6 and 7).

Density per station in Biscayne Bay ranged from 1075 organisms·m² at Station 2 to 24,725 organisms·m² at Station 7 (Table 6; Figures 8 and 9). Densities were generally lower at the nearshore Stations 1-5 (Figures 1). Density per station in Manatee Bay ranged from 150 organisms·m² at Station 23 to 74,050 organisms·m² at Station 25 (Table 6; Figures 8 and 9).

Taxa diversity and evenness for the Biscayne Bay and Manatee Bay stations are given in Table 6 and Figures 10 and 11. Taxa diversity (H') in Biscayne Bay varied considerably and ranged from 1.62 at Station 1 to 3.65 at Station 20 (Table 6; Figure 10). Diversity was lowest at the nearshore stations 1-5. Taxa evenness (J') in Biscayne Bay

also exhibited considerable variation and ranged from 0.56 at Station 15 to 0.88 at Station 16 (Table 6; Figure 11). Taxa diversity (H') in Manatee Bay also varied considerably and ranged from 0.64 at Station 23 to 3.53 at Station 29 (Table 6; Figure 10). Taxa evenness (J') in Manatee Bay also exhibited variation and ranged from 0.24 at Station 25 to 0.92 at Station 23 (Table 6; Figure 11).

QUALITY ASSURANCE STATEMENT

Client/Project NOAA

Work Assignment Title Biscayne Bay and Manatee Bay 1999

Work Assignment Number

Task Number DO 2

Description of Data Set or Deliverable: 30 Benthic macroinvertebrate samples collected

December 1-6, 1999; Young Dredge grabs.

Description of audit and review activities: Judged accuracy rates were well above standard levels for sorting and taxonomy. Laboratory QC reports were completed. Copies of QC results follow (see attachment.) All taxonomic data were entered into computer and printed. This list was checked for accuracy against original taxonomic data sheets.

Description of outstanding issues or deficiencies which may affect data quality: **None**
